The Basic Tool Palette The Tools panel contains the tools you need to draw, copy, crop, text, and create and apply patterns and drawings. (See Figure 1-3 to see the Tools panel.) The basic tools are available by simply clicking them in the palette, or you can click on the tool icon to select it. Tools have keyboard shortcuts, so after you're comfortable with your work, you can start creating your own _mashups_ by using the right combination of tools, just as you can with words and phrases. **Figure 1-3:** The Tools palette is where you can select tools and work with them. The Tools palette (refer to Figure 1-3) is one of the most important buttons in Photoshop. You're going to need it all the time, even though you can use the keyboard to pick a tool and then press Enter to make a selection. You have several tools at your disposal — they're quick, they're easy, and they're fun. And with every tool you add to your toolbox, you become an expert. When you use a Photoshop tool, the tool box displays in the upper-right corner of the Canvas, which is the area covered by the working image (see the center image in Figure 1-3). The tool box is docked on the right side of the Canvas, with the tool options available, such as the Brush tool. (The Brush tool is covered in detail in the next chapter in this book.) In this section, I discuss the tools you need to move, rotate, and resize images. You need these tools to get the most out

Q: How to disable column from MySQL DB when using "Turn Column Into an index"? I have a MySQL table that I want to add an index to using ALTER TABLE ENGINE=MyISAM ADD INDEX (ID). However, when I do this, a column '0' gets added to the table. After looking at this answer, I am aware that I can remove the column using SHOW CREATE TABLE, but it seems cumbersome to do this every time I add an index to a table. Is there a way to only ALTER the table when a column is used as an index? A: We use a table structure like so:

```
CREATE TABLE `table_name` ( `col0` BLOB, `col1` BLOB, `col2` BLOB, `col3` BLOB, `col4` BLOB, `col5` BLOB, `col6` BLOB, `col7` BLOB, `col8` BLOB, `col9` BLOB, `col10` BLOB, `col11` BLOB, `col12` BLOB, `col13` BLOB, `col14` BLOB, `col15` BL

It is desirable in many contexts to filter oil from crude oil in various crude oil wells. This is done particularly when the crude oil includes natural gas which is to be separated from the crude oil. The natural gas is generally volatized at the surface before entering into a production well. After separation at the surface the crude oil that exits the production well typically contains certain amounts of gas, water, and other impurities in addition to crude oil. The oil can be typically separated from the impurities at the surface by changing the mixture, either by heating or by vacuum distillation. When gas and water are not separated, the oil/water mixture is referred to as being "dirty oil". The "dirty oil" may be refined by several different techniques, including dehydration by glycol, solvent dew point systems, floatation, and absorption. However, if the crude oil contains too much water, the resulting oil may be very dangerous to handle and transport. As such, it is important to remove as much water from the crude oil as possible. At least two industry standards exist for separating

gas from crude oil and water. The first standard is API 607, which is commonly referred to as "75% Gas In Crude". This standard is very restrictive and requires most of the water be removed prior to the oil being refined into gasoline. Accordingly, when this standard is applied to crude oil, it is very difficult to achieve a gasoline quality oil with less than 3 to 10 ppm water. A second standard is commonly referred to as "40% Gas In Crude", which is less severe than the API standard. When 40% Gas In Crude standard is applied, if the oil has less than 5 ppm water, it can be refined with a gasoline quality. However, it is very difficult to achieve a 40% Gas In Crude standard with typical methods and systems used in the industry. The industry standards for separating water from oil can be shown in the following table: The industry currently uses a number of techniques to make crude oil more water soluble. For example, when a crude oil is first brought into storage, the heating and quiescent time typically exceeds 3 days. Accordingly, the oil is heated to a temperature at which the oil will become more soluble. The oil will be heated typically by a combination of heating and stirring. Once heated, the oil is allowed to cool for a period to allow the desired amount of water to dissolve into the oil. Once the oil
